# Evaluating a model graphically

SUPERVISED LEARNING IN R: REGRESSION

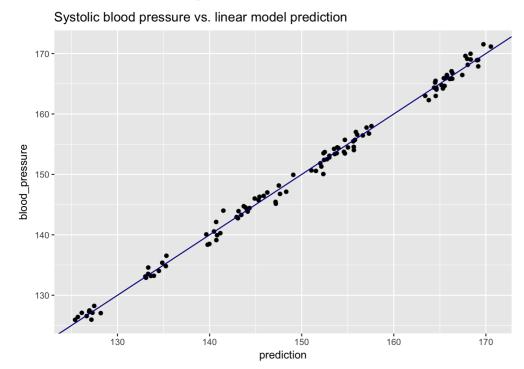

Nina Zumel and John Mount
Win-Vector LLC

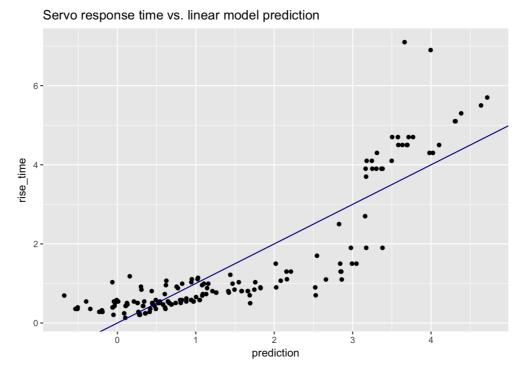

### Plotting Ground Truth vs. Predictions

#### A well fitting model

#### A poorly fitting model

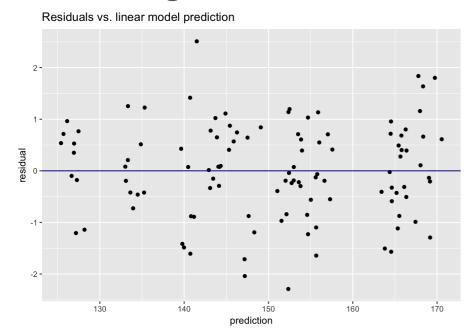

- x = y line runs through center of points
- "line of perfect prediction"

- Points are all on one side of x = y line
- Systematic errors

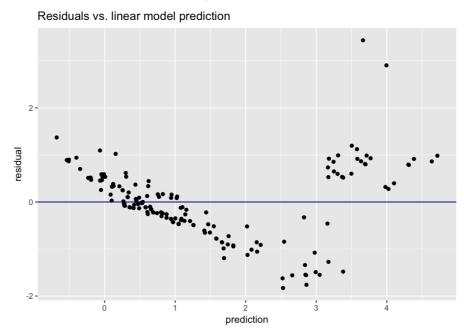

#### The Residual Plot

#### A well fitting model

- Residual: actual outcome prediction
- Good fit: no systematic errors

#### A poorly fitting model

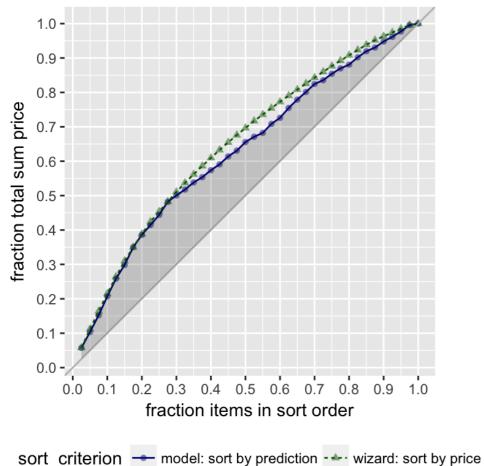

Systematic errors

#### The Gain Curve

#### Home price model price~prediction

relative Gini score: 0.85 alt. hyp.: relGini(prediction)>permuted relGini, p<1e-05

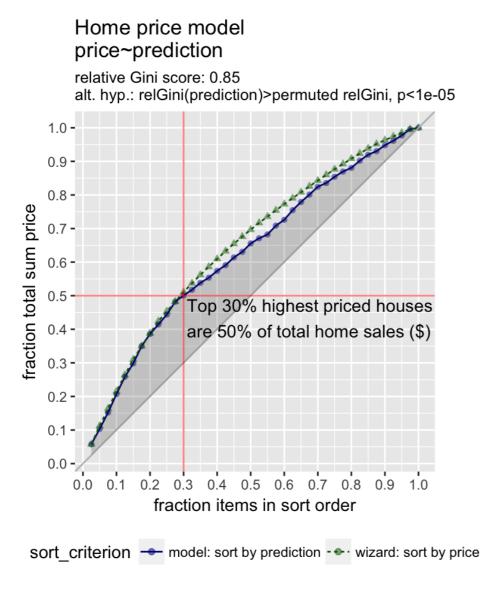

Measures how well model sorts the outcome

- x-axis: houses in modelsorted order (decreasing)
- **y-axis**: fraction of total accumulated home sales

Wizard curve: perfect model

#### Reading the Gain Curve

GainCurvePlot(houseprices, "prediction", "price", "Home price model")

# Let's practice!

SUPERVISED LEARNING IN R: REGRESSION

# Root Mean Squared Error (RMSE)

SUPERVISED LEARNING IN R: REGRESSION

Nina Zumel and John Mount
Win-Vector LLC

## What is Root Mean Squared Error (RMSE)?

$$RMSE = \sqrt{\overline{(pred-y)^2}}$$

where

- pred y: the error, or residuals vector
- $\overline{(pred-y)^2}$ : mean value of  $(pred-y)^2$

#### RMSE of the Home Sales Price Model

```
# Calculate error
err <- houseprices$prediction - houseprices$price</pre>
```

- price : column of actual sale prices (in thousands)
- prediction : column of predicted sale prices (in thousands)

#### RMSE of the Home Sales Price Model

```
# Calculate error
err <- houseprices$prediction - houseprices$price

# Square the error vector
err2 <- err^2</pre>
```

#### RMSE of the Home Sales Price Model

```
# Calculate error
err <- houseprices$prediction - houseprices$price

# Square the error vector
err2 <- err^2

# Take the mean, and sqrt it
(rmse <- sqrt(mean(err2)))</pre>
```

58.33908

•  $RMSE \approx 58.3$ 

### Is the RMSE Large or Small?

```
# Take the mean, and sqrt it
(rmse <- sqrt(mean(err2)))</pre>
```

#### 58.33908

```
# The standard deviation of the outcome
(sdtemp <- sd(houseprices$price))</pre>
```

#### 135.2694

- $RMSE \approx 58.3$
- $sd(price) \approx 135$

# Let's practice!

SUPERVISED LEARNING IN R: REGRESSION

# R-Squared ( $R^2$ )

SUPERVISED LEARNING IN R: REGRESSION

Nina Zumel and John Mount
Win-Vector LLC

## What is $\mathbb{R}^2$ ?

A measure of how well the model fits or explains the data

- A value between 0-1
  - near 1: model fits well
  - near 0: no better than guessing the average value

## Calculating $\mathbb{R}^2$

 ${\cal R}^2$  is the variance explained by the model.

$$R^2 = 1 - rac{RSS}{SS_{Tot}}$$

where

- $RSS = \sum (y prediction)^2$ 
  - Residual sum of squares (variance from model)
- $SS_{Tot} = \sum (y \overline{y})^2$ 
  - Total sum of squares (variance of data)

## Calculate $\mathbb{R}^2$ of the House Price Model: RSS

Calculate error

```
err <- houseprices$prediction - houseprices$price
```

Square it and take the sum

```
rss <- sum(err^2)
```

- price : column of actual sale prices (in thousands)
- pred: column of predicted sale prices (in thousands)
- $RSS \approx 136138$

## Calculate $R^2$ of the House Price Model: $SS_{Tot}$

• Take the difference of prices from the mean price

```
toterr <- houseprices$price - mean(houseprices$price)</pre>
```

• Square it and take the sum

```
sstot <- sum(toterr^2)</pre>
```

- $RSS \approx 136138$
- $SS_{Tot} \approx 713615$

## Calculate $\mathbb{R}^2$ of the House Price Model

```
(r_squared <- 1 - (rss/sstot) )</pre>
```

#### 0.8092278

- $RSS \approx 136138$
- $SS_{Tot} \approx 713615$
- $R^2 \approx 0.809$

## Reading $R^2$ from the lm() model

```
# From summary()
summary(hmodel)
Residual standard error: 60.66 on 37 degrees of freedom
Multiple R-squared: 0.8092, Adjusted R-squared: 0.7989
F-statistic: 78.47 on 2 and 37 DF, p-value: 4.893e-14
summary(hmodel)$r.squared
0.8092278
# From glance()
glance(hmodel)$r.squared
0.8092278
```

### Correlation and ${\mathbb R}^2$

rho <- cor(houseprices\$prediction, houseprices\$price)</pre>

#### 0.8995709

rho^2

#### 0.8092278

- $\rho$  = cor(prediction, price) = 0.8995709
- $\rho^2 = 0.8092278 = R^2$

## Correlation and ${\mathbb R}^2$

- True for models that minimize squared error:
  - Linear regression
  - GAM regression
  - Tree-based algorithms that minimize squared error
- True for training data; **NOT** true for future application data

# Let's practice!

SUPERVISED LEARNING IN R: REGRESSION

# Properly Training a Model

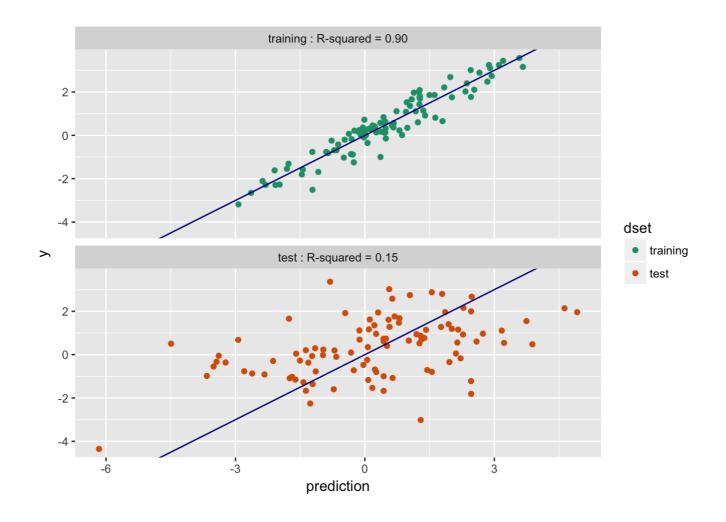

SUPERVISED LEARNING IN R: REGRESSION

Nina Zumel and John Mount Win-Vector, LLC

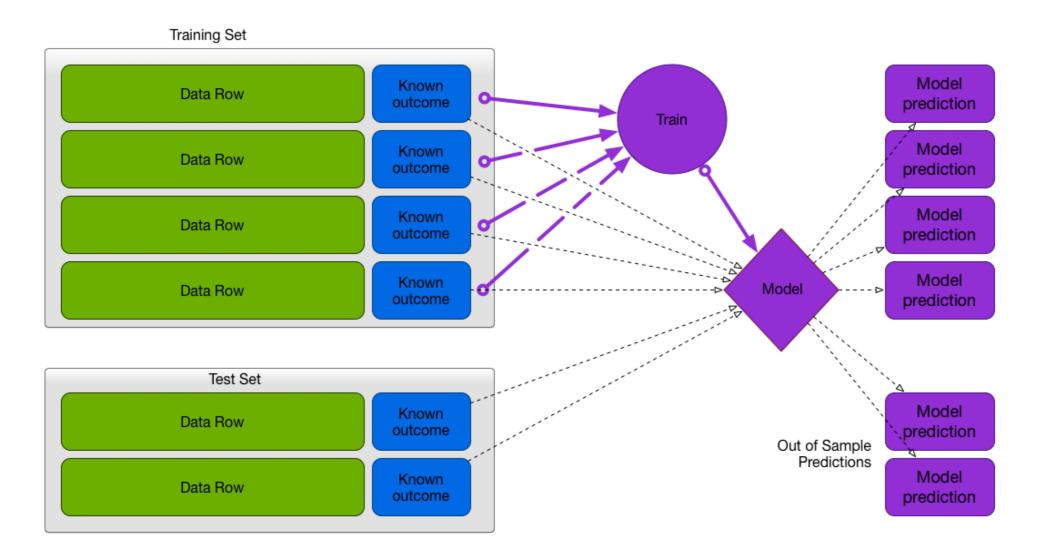

# Models can perform much better on training than they do on future data.

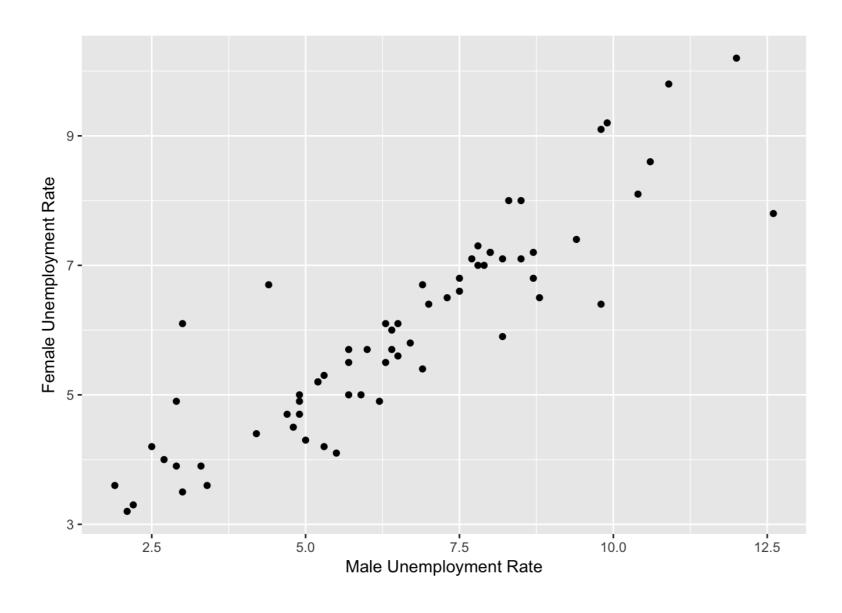

• Training  $R^2$ : 0.9; Test  $R^2$ : 0.15 -- Overfit

### **Test/Train Split**

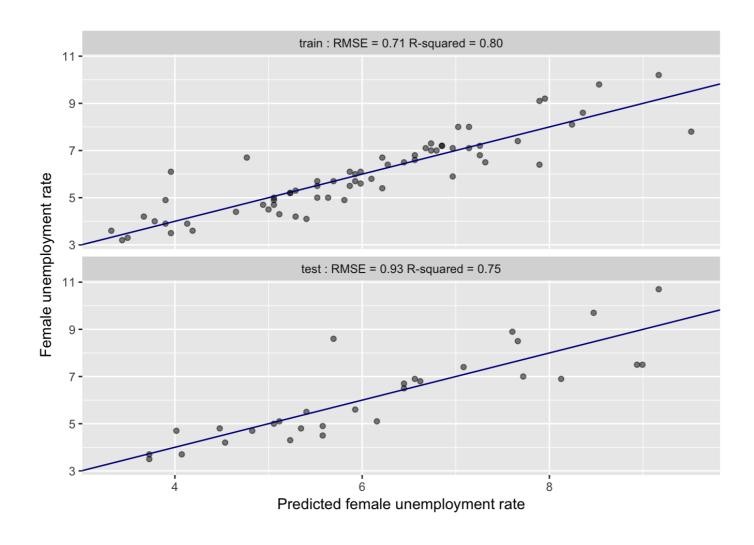

Recommended method when data is plentiful

## **Example: Model Female Unemployment**

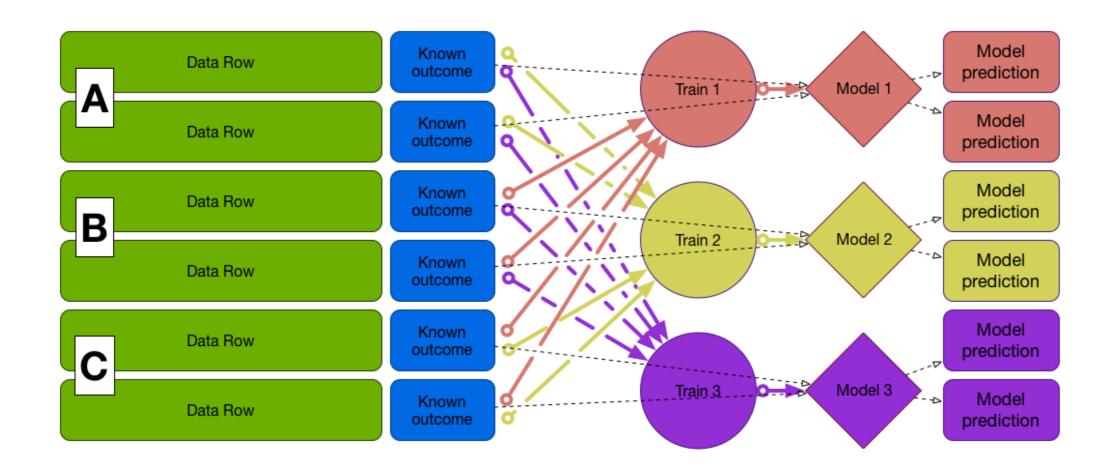

Train on 66 rows, test on 30 rows

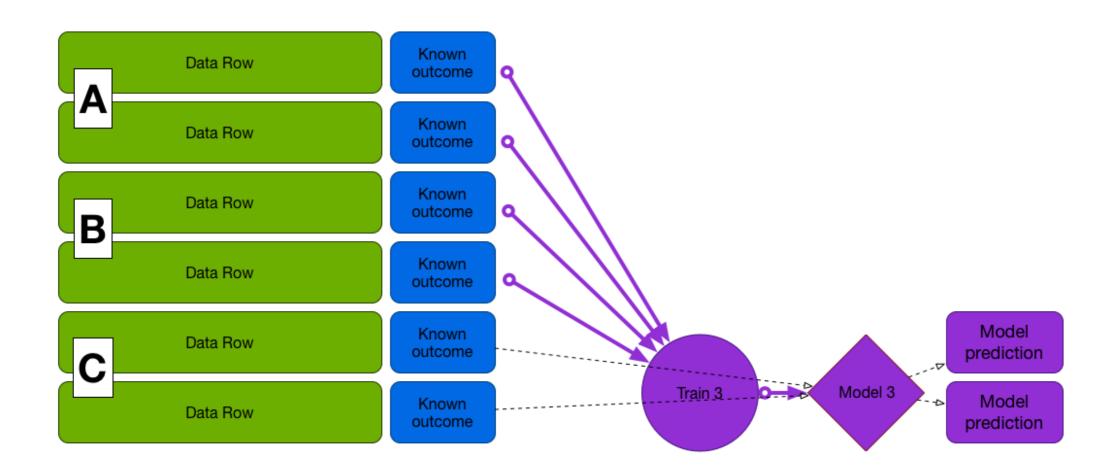

#### Model Performance: Train vs. Test

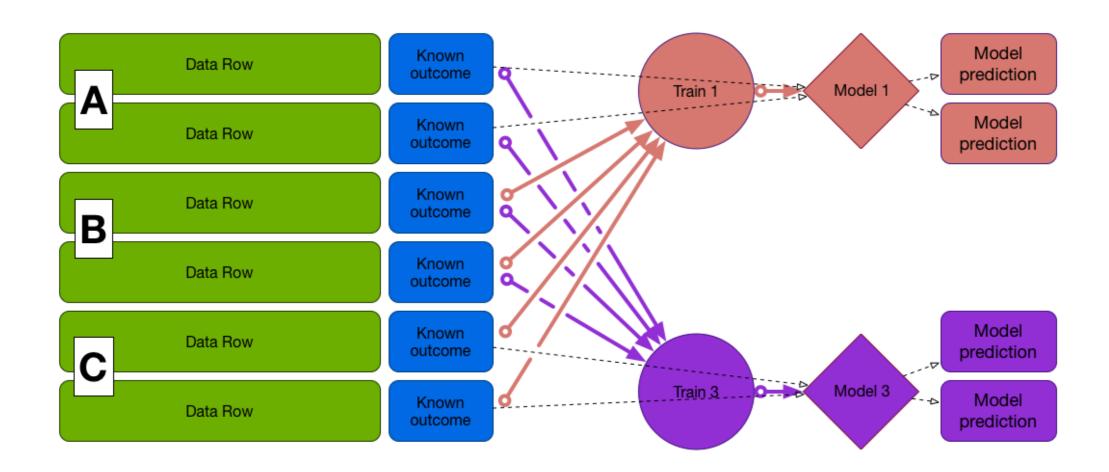

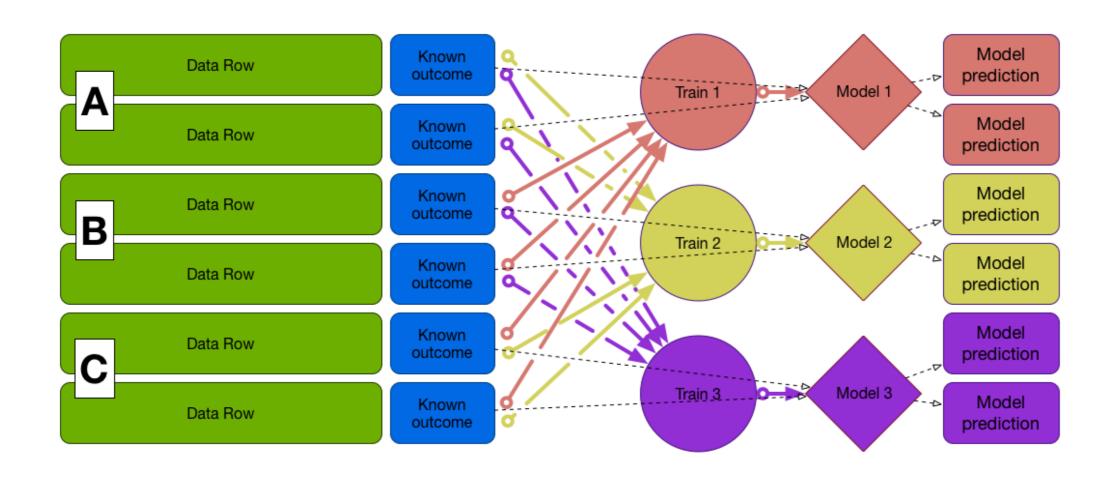

- Training: RMSE 0.71,  $\mathbb{R}^2$  0.8
- $\bullet \quad \text{Test: RMSE 0.93, } R^2 \text{ 0.75}$

Preferred when data is not large enough to split off a test set

#### Create a cross-validation plan

```
library(vtreat)
splitPlan <- kWayCrossValidation(nRows, nSplits, NULL, NULL)</pre>
```

- nRows: number of rows in the training data
- nSplits: number folds (partitions) in the cross-validation
  - e.g, nfolds = 3 for 3-way cross-validation
- remaining 2 arguments not needed here

#### Create a cross-validation plan

```
library(vtreat)
splitPlan <- kWayCrossValidation(10, 3, NULL, NULL)</pre>
```

First fold (A and B to train, C to test)

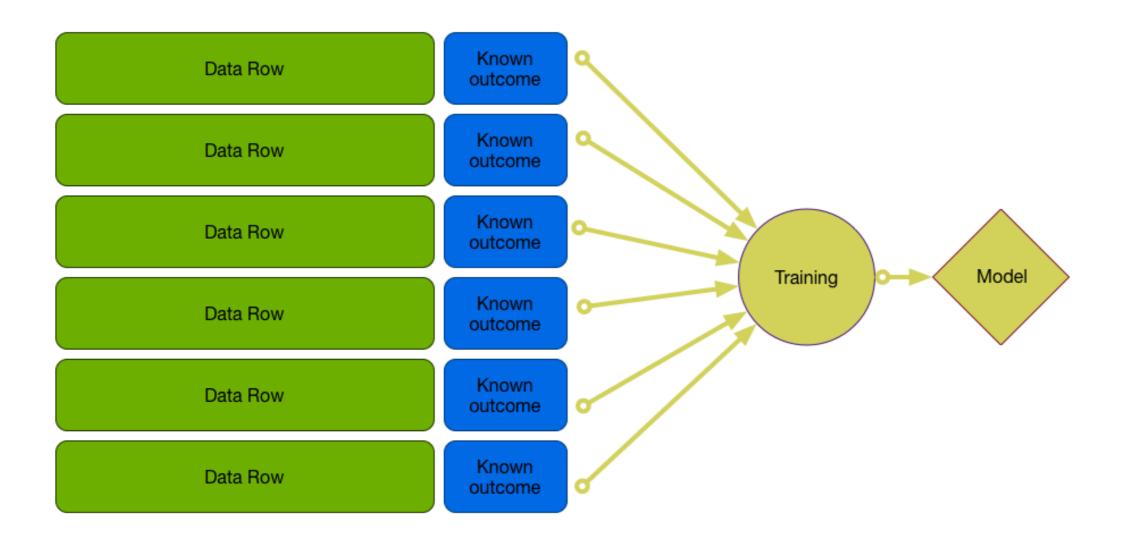

```
splitPlan[[1]]
```

```
$train
1 2 4 5 7 9 10
$app
3 6 8
```

Train on A and B, test on C, etc...

```
split <- splitPlan[[1]]
model <- lm(fmla, data = df[split$train,])
df$pred.cv[split$app] <- predict(model, newdata = df[split$app,])</pre>
```

#### Final Model

## **Example: Unemployment Model**

Measure type	RMSE	$R^2$
train	0.7082675	0.8029275
test	0.9349416	0.7451896
cross-validation	0.8175714	0.7635331
